**Abstract.** In this review article, we will develop the perturbative framework for the calculation of hard scattering processes. We will undertake to provide both a reasonably rigorous development of the formalism of hard scattering of quarks and gluons as well as an intuitive understanding of the physics behind the scattering. We will emphasize the role of logarithmic corrections as well as power counting in  $\alpha_s$  in order to understand the behaviors of hard scattering processes. We will include “rules of thumb” as well as “official recommendations”, and where possible will seek to dispel some myths. We will also discuss the impact of soft processes on the measurements of hard scattering processes. Experiences that have been gained at the Fermilab Tevatron will be recounted and, where appropriate, extrapolated to the LHC.

1. Introduction

Scattering processes at high energy hadron colliders can be classified as either hard or soft. Quantum Chromodynamics (QCD) is the underlying theory for all such processes, but the approach and level of understanding is very different for the two cases. For hard processes, e.g. Higgs or high  $p_T$  jet production, the rates and event properties

# discoveries

Higgs discovery at LHC

SUSY discovery at LHC

# What can we calculate?

Scattering processes at high energy hadron colliders can be classified as either **HARD** or **SOFT**

Quantum Chromodynamics (QCD) is the underlying theory for **all** such processes, but the approach (and the level of understanding) is very different for the two cases

For **HARD** processes, e.g.  $W$  or high- $E_T$  jet production, the rates and event properties can be predicted with some precision using **perturbation theory**

For **SOFT** processes, e.g. the **total cross section** or **diffractive** processes, the rates and properties are dominated by **non-perturbative** QCD effects, which are much less well understood

proton - (anti)proton cross sections

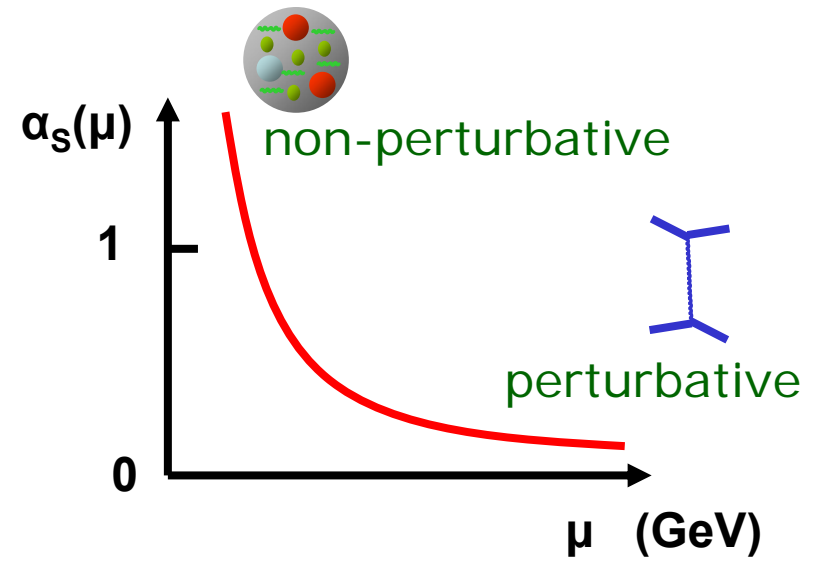

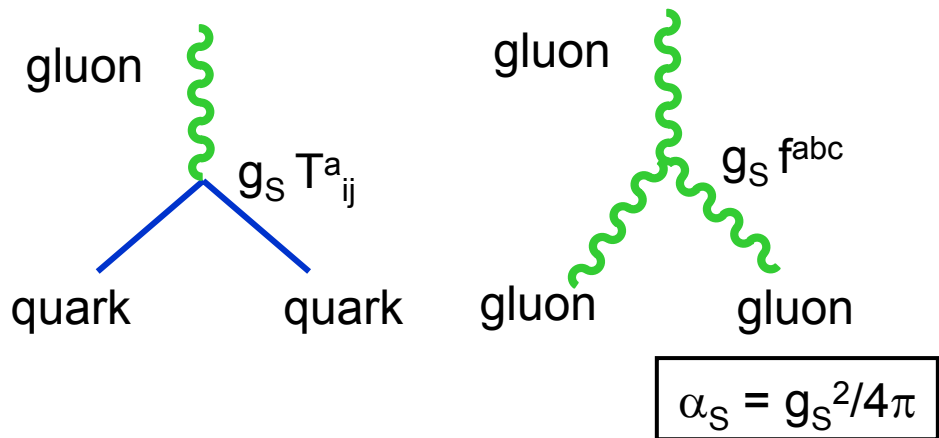

# Outline

- **Basics: QCD, partons, pdfs**
  - basic parton model ideas for DIS
  - scaling violation & DGLAP
  - parton distribution functions
- **Application to hadron colliders**
  - hard scattering & basic kinematics
  - the Drell Yan process in the parton model
  - order  $\alpha_s$  corrections to DY, singularities, factorisation
  - examples of other hard processes and their phenomenology
  - parton luminosity functions
  - uncertainties in the calculations
- **Beyond fixed-order inclusive cross sections**
  - Sudakov logs and resummation
  - parton showering models (basic concepts only!)
  - the role of non-perturbative contributions: intrinsic  $k_T$ ,
  - underlying event/minimum bias contributions
  - theoretical frontiers: exclusive production of Higgs

# Basics of QCD

- renormalisation of the coupling

$$\frac{\mu^2}{\alpha_s(\mu^2)} \frac{\partial \alpha_s(\mu^2)}{\partial \mu^2} = -\frac{\alpha_s(\mu^2)}{4\pi} \beta_0 - \left(\frac{\alpha_s(\mu^2)}{4\pi}\right)^2 \beta_1 - \left(\frac{\alpha_s(\mu^2)}{4\pi}\right)^3 \beta_2 + \dots$$

$$\beta_0 = 11 - \frac{2}{3}n_f, \quad \beta_1 = 102 - \frac{38}{3}n_f, \quad \dots$$

- colour matrix algebra

$$[T^a, T^b] = i f^{abc} T^c, \quad (T^a T^a)_{ij} = C_F \delta_{ij} = 4/3 \delta_{ij}, \quad \text{Tr}(T^a T^b) = T_F \delta^{ab} = 1/2 \delta^{ab}, \quad \dots$$

## Asymptotic Freedom

“What this year's Laureates discovered was something that, at first sight, seemed completely contradictory. The interpretation of their mathematical result was that the closer the quarks are to each other, the *weaker* is the 'colour charge'. When the quarks are really close to each other, the force is so weak that they behave almost as free particles. This phenomenon is called ‘asymptotic freedom’. The converse is true when the quarks move apart: the force becomes stronger when the distance increases.”

# deep inelastic scattering and the parton model

- variables

$$Q^2 = -q^2 \quad (\text{resolution})$$

$$x = Q^2 / 2p \cdot q \quad (\text{inelasticity})$$

- structure functions

$$d\sigma/dx dQ^2 \propto \alpha^2 Q^{-4} F_2(x, Q^2)$$

- (Bjorken) scaling

$$F_2(x, Q^2) \rightarrow F_2(x) \quad (\text{SLAC, } \sim 1970)$$

# the parton model (Feynman 1969)

- photon scatters incoherently off massless, pointlike, spin-1/2 **quarks**
- probability that a quark carries fraction  $\xi$  of parent proton's momentum is  $q(\xi)$ , ( $0 < \xi < 1$ )

infinite  
momentum  
frame

$$F_2(x) = \sum_{q,\bar{q}} \int_0^1 d\xi e_q^2 \xi q(\xi) \delta(x-\xi) = \sum_{q,\bar{q}} e_q^2 x q(x)$$
$$= \frac{4}{9} x u(x) + \frac{1}{9} x d(x) + \frac{1}{9} x s(x) + \dots$$

- the functions  $u(x)$ ,  $d(x)$ ,  $s(x)$ , ... are called **parton distribution functions** (pdfs) - they encode information about the proton's deep structure

# extracting pdfs from experiment

- different beams  
( $e, \mu, \nu, \dots$ ) & targets  
( $H, D, Fe, \dots$ ) measure  
different combinations of  
quark pdfs
- thus the individual  $q(x)$   
can be extracted from a  
set of structure function  
measurements
- gluon not measured  
directly, but carries  
about 1/2 the proton's  
momentum

$$F_2^{ep} = \frac{4}{9}(u + \bar{u}) + \frac{1}{9}(d + \bar{d}) + \frac{1}{9}(s + \bar{s}) + \dots$$

$$F_2^{en} = \frac{1}{9}(u + \bar{u}) + \frac{4}{9}(d + \bar{d}) + \frac{1}{9}(s + \bar{s}) + \dots$$

$$F_2^{vp} = 2 \left[ d + s + \bar{u} + \dots \right]$$

$$F_2^{vn} = 2 \left[ u + \bar{d} + \bar{s} + \dots \right]$$

$$s = \bar{s} = \frac{5}{6} F_2^{vN} - 3 F_2^{eN}$$

$$\sum_q \int_0^1 dx x (q(x) + \bar{q}(x)) = 0.55$$

# 35 years of Deep Inelastic Scattering

p (920 GeV)

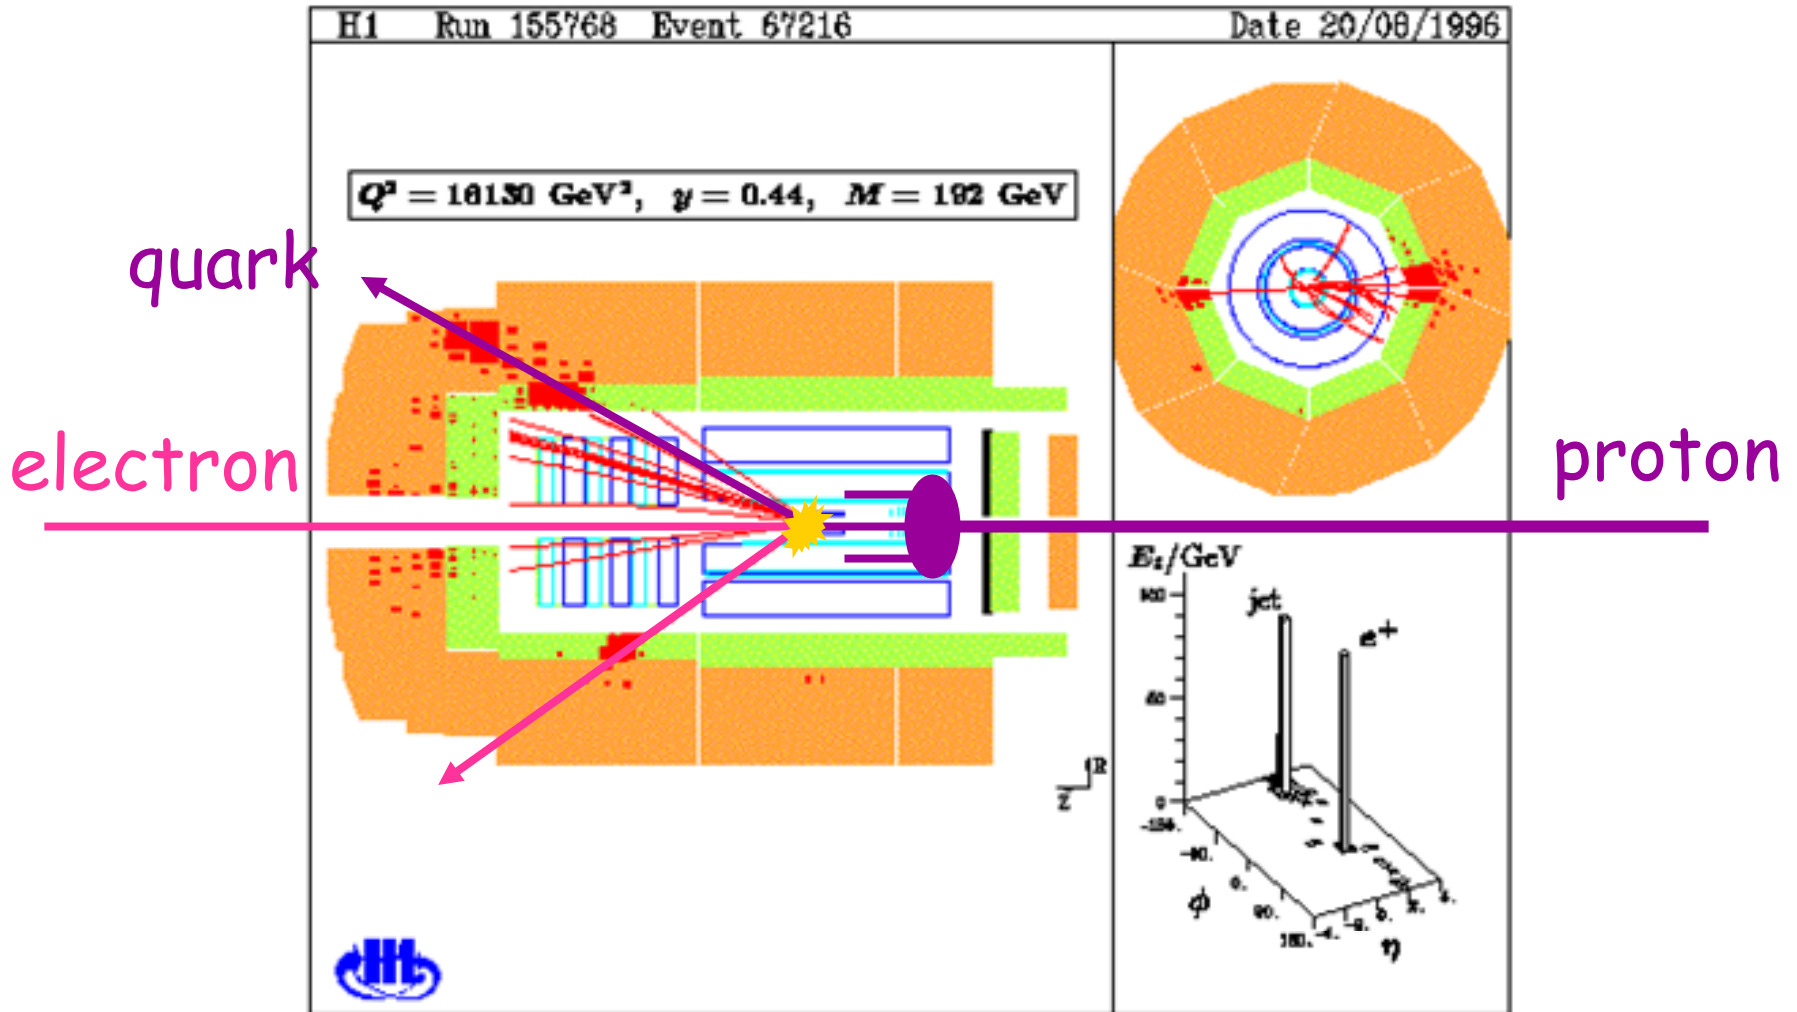

EXPERIMENT  
AT HERA

CEEN

# a deep inelastic scattering event at HERA

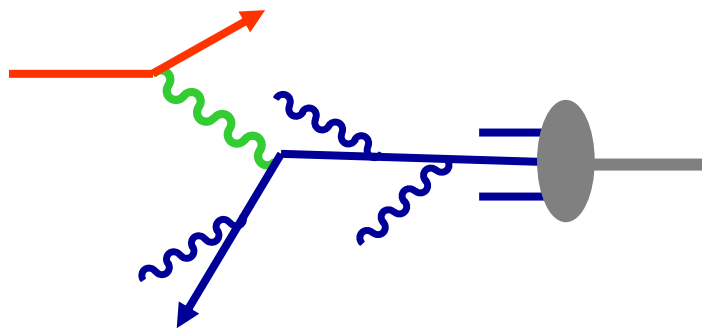

# 35 years of Deep Inelastic Scattering

# scaling violations and QCD

The structure function data exhibit systematic violations of Bjorken scaling:

quarks emit gluons!

$F_2$

$$\longrightarrow \hat{F}_2 = e_q^2 \delta(1-x) + e_q^2 \frac{\alpha_S}{2\pi} x \left[ P(x) \ln(Q^2/\kappa^2) + C(x) \right]$$

where the logarithm comes from  $\int_0^{\sim Q^2} \frac{dk_T^2}{k_T^2} \rightarrow \int_{\kappa^2}^{\sim Q^2} \frac{dk_T^2}{k_T^2} \rightarrow \ln(Q^2/\kappa^2)$   
 ('collinear singularity') and

$$P(x) = C_F \left[ \frac{1+x^2}{(1-x)_+} + \frac{3}{2} \delta(1-x) \right]$$

$$\int_0^1 dx = \frac{f(x)}{(1-x)_+} = \int_0^1 \frac{f(x) - f(1)}{1-x}$$

then convolute with a 'bare' quark distribution in the proton:

$$F_2(x, Q^2) = x \sum_q e_q^2 \left[ q_0(x) + \frac{\alpha_S}{2\pi} \int_x^1 \frac{dy}{y} q_0(y) \left\{ P(x/y) \ln(Q^2/\kappa^2) + C(x/y) \right\} \right]$$

next, factorise the collinear divergence into a 'renormalised' quark distribution, by introducing the factorisation scale  $\mu^2$  :

$$q(x, \mu^2) = q_0(x) + \frac{\alpha_S}{2\pi} \int_x^1 \frac{dy}{y} q_0(y) \left\{ P(x/y) \ln(\mu^2/\kappa^2) + \bar{C}(x/y) \right\}$$

then  $\frac{1}{x} F_2(x, Q^2) = x \sum_q e_q^2 \int_x^1 \frac{dy}{y} q(y, \mu^2) \left\{ \delta\left(1 - \frac{x}{y}\right) + \frac{\alpha_s}{2\pi} \left( P(x/y) \ln(Q^2/\mu^2) + C_q(x/y) \right) \right\}$

finite, by construction

note arbitrariness of  $C_q = C - \bar{C} \rightarrow$  'factorisation scheme dependence'

we can choose  $\bar{C}$  such that  $C_q = 0$ , the DIS scheme, or use dimensional regularisation and remove the poles at  $N=4$ , the  $\overline{\text{MS}}$  scheme, with  $C_q \neq 0$

$q(x, \mu^2)$  is not calculable in perturbation theory,\* but its scale ( $\mu^2$ ) dependence is:

$$\mu^2 \frac{\partial}{\partial \mu^2} q(x, \mu^2) = \frac{\alpha_S(\mu^2)}{2\pi} \int_x^1 \frac{dy}{y} q(y, \mu^2) P(x/y)$$

Dokshitzer  
Gribov  
Lipatov  
Altarelli  
Parisi

\*lattice QCD?

note that we are free to choose  $\mu^2 = Q^2$  in which case

$$\frac{1}{x}F_2(x, Q^2) = x \sum_q e_q^2 \int_x^1 \frac{dy}{y} q(y, Q^2) \left\{ \delta\left(1 - \frac{x}{y}\right) + \frac{\alpha_s}{2\pi} C_q(x/y) \right\}$$

coefficient function,  
see QCD book

... and thus the scaling violations of the structure function follow those of  $q(x, Q^2)$  predicted by the DGLAP equation:

the rate of change of  $F_2$  is proportional to  $\alpha_s$  (DGLAP), hence structure function data can be used to measure the strong coupling!

however, we must also include the gluon contribution

$$\frac{1}{x}F_2(x, Q^2) = x \sum_q e_q^2 \int_x^1 \frac{dy}{y} q(y, Q^2) \left\{ \delta\left(1 - \frac{x}{y}\right) + \frac{\alpha_s(Q^2)}{2\pi} C_q(x/y) \right\} + x \sum_q e_q^2 \frac{\alpha_s(Q^2)}{2\pi} \int_x^1 \frac{dy}{y} g(y, Q^2) C_g(x/y)$$

coefficient functions  
- see QCD book

... and with additional terms in the DGLAP equations

$$\mu^2 \frac{\partial q_i(x, \mu^2)}{\partial \mu^2} = \frac{\alpha_S(\mu^2)}{2\pi} (P^{qq} * q_i + 2n_f P^{qg} * g)$$

$$\mu^2 \frac{\partial g(x, \mu^2)}{\partial \mu^2} = \frac{\alpha_S(\mu^2)}{2\pi} (P^{gq} * \sum_i q_i + P^{gg} * g)$$

$q_i = u, \bar{u}, d, \bar{d}, \dots$

\* = convolution integral

note that at small (large)  $x$ , the gluon (quark) contribution dominates the evolution of the quark distributions, and therefore of  $F_2$

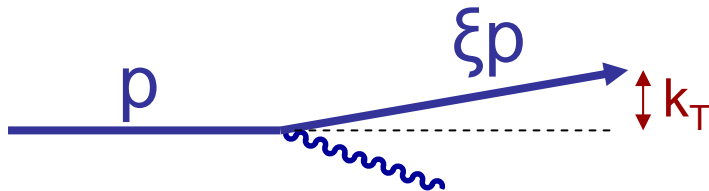

$$\begin{aligned} P^{qq} &= \frac{4}{3} \left( \frac{1+x^2}{1-x} \right)_+ && \text{splitting functions} \\ P^{qg} &= \frac{1}{2} (x^2 + (1-x)^2) \\ P^{gq} &= \frac{4}{3} \left( \frac{1+(1-x)^2}{x} \right) \\ P^{gg} &= 6 \left( \frac{1-x}{x} + x(1-x) + \left( \frac{x}{1-x} \right)_+ \right) \\ &\quad - \left( \frac{1}{2} + \frac{n_f}{3} \right) \delta(1-x) \end{aligned}$$

# DGLAP evolution: physical picture

Altarelli, Parisi (1977)

- a fast-moving quark loses momentum by emitting a gluon:

$$d\mathcal{P} \simeq \frac{\alpha_S(k_T^2)}{2\pi} \frac{dk_T^2}{k_T^2} P^{qq}(\xi) d\xi$$

- ... with phase space  $k_T^2 < O(Q^2)$ , hence

$$d\mathcal{P} \simeq \frac{\alpha_S}{2\pi} \ln Q^2 P^{qq}(\xi) d\xi$$

- similarly for other splittings

$$\sim P^{gq}$$

- the combination of all such probabilistic splittings correctly generates the leading-logarithm approximation to the all-orders in pQCD solution of the DGLAP equations

basis of parton  
shower Monte Carlos!

# parton distribution functions

- the bulk of the information on pdfs comes from fitting DIS structure function data, although hadron-hadron collisions data also provide important constraints (see later)
- pdfs are useful in two ways:
  - they are essential for predicting hadron collider cross sections, e.g.

$$\sigma_H \propto [g(x \simeq M_H/\sqrt{s}, M_H^2)]^2$$

- they give us detailed information on the quark flavour content of the nucleon
- no need to solve the DGLAP equations each time a pdf is needed; high-precision approximations obtained from ‘**global fits**’ are available ‘off the shelf’, e.g.

```
SUBROUTINE MRST(X,Q,U,UBAR,D,DBAR... ,BBAR,G)
```

input |

output

# how pdfs are obtained

- choose a factorisation scheme (e.g. MSbar), an order in perturbation theory (see below, e.g. LO, NLO, NNLO) and a 'starting scale'  $Q_0$  where pQCD applies (e.g. 1-2 GeV)
- parametrise the quark and gluon distributions at  $Q_0$ , e.g.

$$f_i(x, Q_0^2) = A_i x^{a_i} [1 + b_i \sqrt{x} + c_i x] (1 - x)^{d_i}$$

- solve DGLAP equations to obtain the pdfs at any  $x$  and scale  $Q > Q_0$ ; fit data for parameters  $\{A_i, a_i, \dots, \alpha_S\}$
- approximate the exact solutions (e.g. interpolation grids, expansions in polynomials etc) for ease of use

# pdfs from global fits - summary

 Questions and Comments to [m.r.walley@durham.ac.uk](mailto:m.r.walley@durham.ac.uk)  
Updated: Dec 11, 2002

# beyond lowest order in pQCD

going to higher orders in pQCD is straightforward in principle, since the above structure for  $F_2$  and for DGLAP generalises in a straightforward way:

$$\begin{aligned}\frac{\partial q_i(x, Q^2)}{\partial \log Q^2} &= \frac{\alpha_S}{2\pi} \int_x^1 \frac{dy}{y} \left\{ P_{q_i q_j}(y, \alpha_S) q_j\left(\frac{x}{y}, Q^2\right) \right. \\ &\quad \left. + P_{q_i g}(y, \alpha_S) g\left(\frac{x}{y}, Q^2\right) \right\} \\ \frac{\partial g(x, Q^2)}{\partial \log Q^2} &= \frac{\alpha_S}{2\pi} \int_x^1 \frac{dy}{y} \left\{ P_{g q_j}(y, \alpha_S) q_j\left(\frac{x}{y}, Q^2\right) \right. \\ &\quad \left. + P_{g g}(y, \alpha_S) g\left(\frac{x}{y}, Q^2\right) \right\}\end{aligned}$$

1972-77

1977-80

2004

DGLAP: 
$$P(x, \alpha_S) = P^{(0)} + \alpha_S P^{(1)}(x) + \alpha_S^2 P^{(2)}(x) + \dots$$

Eq. (3.10)–(3.13) represent new results of this article, with the only exception of the  $C_A \gamma^2$  part of Eq. (3.13) which has been obtained by Beisert and Gracey in Ref. [61]. Our results agree with the even moments  $N = 2, \dots, 12$  computed before [25, 26] using the MCFER program [41, 42].

The results (3.5)–(3.13) are assembled, after inserting the QCD values  $C_F = 4/3$  and  $C_A = 3$  for the colour factor, in Figs. 1 and 2 for four active flavours and a typical value  $\alpha_s = 0.2$  for the strong coupling constant. The 1LO correction are markedly smaller than the 1LO contribution under these circumstances. At  $N > 2$  they amount to less than 2% and 1% for the large diagonal quantities  $\gamma_{\overline{15}}$  and  $\gamma_{\overline{15}}$ , respectively, while for the much smaller off-diagonal anomalous dimension  $\gamma_{\overline{15}}$  and  $\gamma_{\overline{15}}$  values of up to 6% and 4% are reached. The relative 1LO corrections are very large at  $N = 2$  for  $\gamma_{\overline{15}}$ , which is however completely negligible in this region of  $N$ .

For  $N \rightarrow \infty$  the off-diagonal  $n$ -loop anomalous dimension vanish like  $\frac{1}{N} \ln^{n+2} N$ , while the diagonal quantities behave as [62]

$$\gamma_{\overline{15}}^{(n-1)}(N) = A_n^{\overline{15}}(\ln N + \gamma_E) - B_n^{\overline{15}} - C_n^{\overline{15}} \frac{\ln N}{N} + o\left(\frac{1}{N}\right) \quad (3.14)$$

where  $\gamma_E$  is the Euler-Mascheroni constant. The leading large- $N$  coefficients  $A_n^{\overline{15}}$  of  $\gamma_{\overline{15}}$  have been

anomalous dimensions (moments):  $\gamma_N = \int_0^1 dx x^{N-1} P(x)$

- and for the structure functions...

$$\frac{1}{x}F_2(x, Q^2) = x \sum_q e_q^2 \int_x^1 \frac{dy}{y} q(y, Q^2) \left\{ \delta\left(1 - \frac{x}{y}\right) + \frac{\alpha_s(Q^2)}{2\pi} C_q^{(1)}(x/y) \right\}$$

$$x \sum_q e_q^2 \frac{\alpha_s(Q^2)}{2\pi} \int_x^1 \frac{dy}{y} g(y, Q^2) C_g^{(1)}(x/y) + \mathcal{O}(\alpha_s^2(Q^2))$$

... where up to and including the  $\mathcal{O}(\alpha_s^3)$  coefficient functions are known

- terminology:

- LO:  $P^{(0)}$
- NLO:  $P^{(0,1)}$  and  $C^{(1)}$
- NNLO:  $P^{(0,1,2)}$  and  $C^{(1,2)}$

- the more pQCD orders are included, the weaker the dependence on the (unphysical) factorisation scale,  $\mu_F^2$

– and also the (unphysical) renormalisation scale,  $\mu_R^2$ ; note above has  $\mu_R^2 = Q^2$

# What can we calculate?

Scattering processes at high energy hadron colliders can be classified as either **HARD** or **SOFT**

Quantum Chromodynamics (QCD) is the underlying theory for **all** such processes, but the approach (and the level of understanding) is very different for the two cases

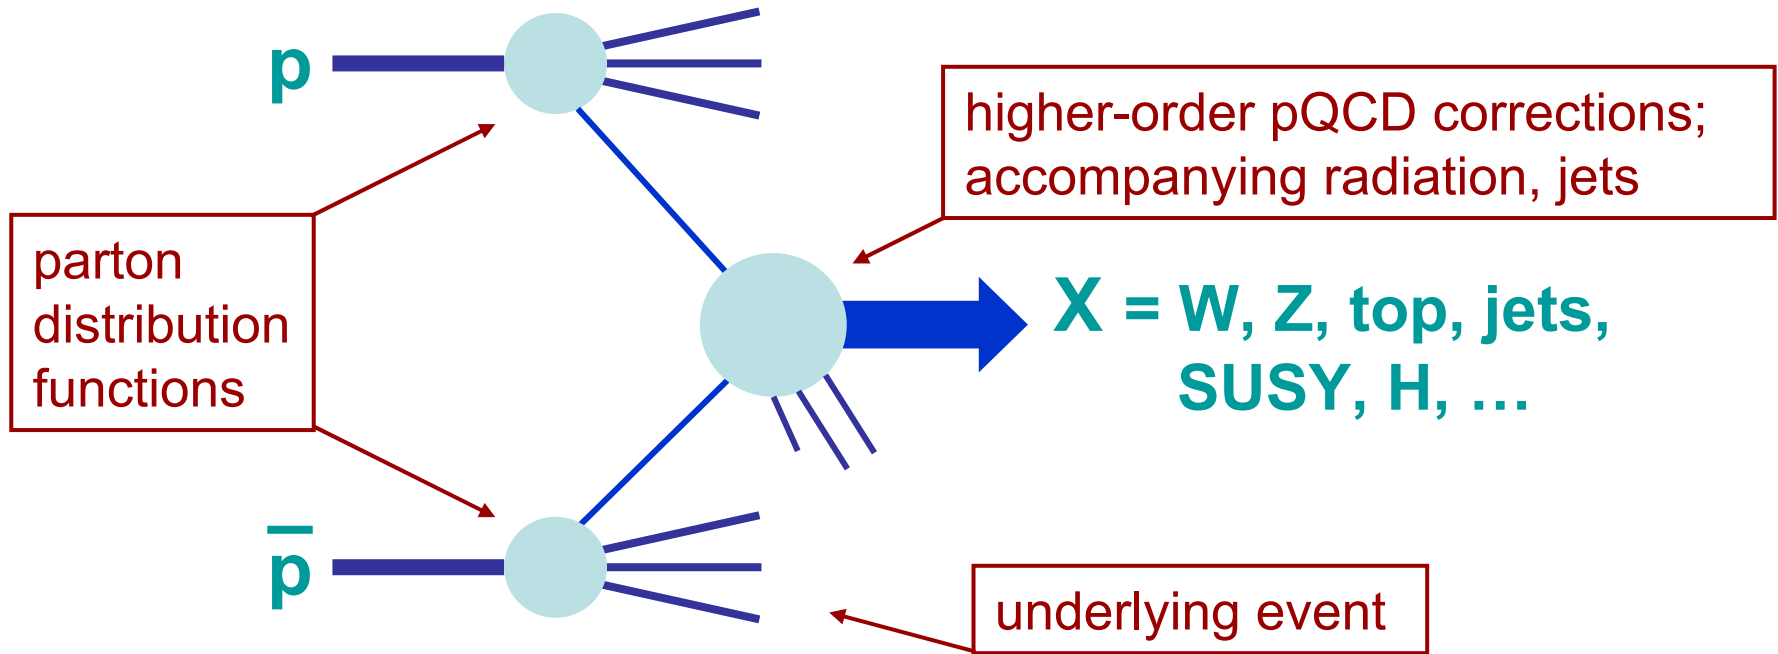

For **HARD** processes, e.g.  $W$  or high- $E_T$  jet production, the rates and event properties can be predicted with some precision using **perturbation theory**

For **SOFT** processes, e.g. the **total cross section** or **diffractive** processes, the rates and properties are dominated by **non-perturbative** QCD effects, which are much less well understood

proton - (anti)proton cross sections

# hard scattering in hadron-hadron collisions

for inclusive production, the basic calculational framework is provided by the QCD FACTORISATION THEOREM:

$$\sigma_X = \sum_{a,b} \int_0^1 dx_1 dx_2 f_a(x_1, \mu_F^2) f_b(x_2, \mu_F^2) \times \hat{\sigma}_{ab \rightarrow X} \left( x_1, x_2, \{p_i^\mu\}; \alpha_S(\mu_R^2), \alpha(\mu_R^2), \frac{Q^2}{\mu_R^2}, \frac{Q^2}{\mu_F^2} \right)$$

# kinematics

- collision energy:  $\sqrt{s}$
- parton momenta:  
 $p_1^\mu = x_1 \sqrt{s}/2 (1, 0, 0, 1)$   
 $p_2^\mu = x_2 \sqrt{s}/2 (1, 0, 0, -1)$
- invariant mass:  $M^2 = (p_1 + p_2)^2 \equiv \hat{s} = x_1 x_2 s$
- rapidity:  $y = \frac{1}{2} \log \frac{E + p_z}{E - p_z} = \frac{1}{2} \log \frac{x_1}{x_2} \Rightarrow \frac{x_1}{x_2} = e^{2y}$

$$x_1 = \frac{M}{\sqrt{s}} e^y, \quad x_2 = \frac{M}{\sqrt{s}} e^{-y}$$

# early history: the Drell-Yan process

$$\begin{aligned} \frac{d^2\sigma}{dM^2} &= \frac{4\pi\alpha^2}{3M^4} \int_0^1 dx_1 dx_2 \delta(x_1 x_2 - \tau) \sum_a e_a^2 f_a(x_1) f_{\bar{a}}(x_2) \\ &= \frac{4\pi\alpha^2}{3M^4} \mathcal{F}(\tau) \quad (\text{scaling}) \end{aligned}$$

“The full range of processes of the type  $A + B \rightarrow \mu^+ \mu^- + X$  with incident  $p, \pi, K, \gamma$  etc affords the interesting possibility of comparing their parton and antiparton structures” (Drell and Yan, 1970)

(nowadays) ... and to study the scattering of quarks and gluons, and how such scattering creates **new particles**

# jets! (1981)

## OBSERVATION OF JETS IN HIGH TRANSVERSE ENERGY EVENTS AT THE CERN PROTON ANTIPROTON COLLIDER

UA1 Collaboration, CERN, Geneva, Switzerland

Transverse energy flow of the 5 events with  $\sum E_T > 100$  GeV

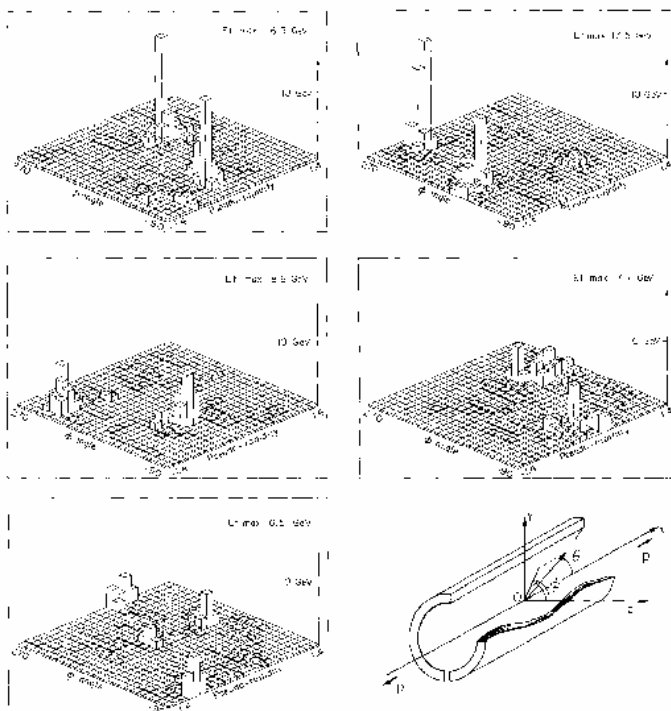

Fig. 3. Distribution of transverse energy versus azimuth  $\phi$  and pseudorapidity  $\eta$ , for the five events with the highest  $\sum E_T$

e.g. two gluons scattering at wide angle

# factorisation

- the factorisation of ‘hard scattering’ cross sections into products of parton distributions was experimentally confirmed and theoretically plausible
- however, it was not at all obvious in QCD (i.e. with quark–gluon interactions included)

- in QCD, for any hard, inclusive process, the soft, nonperturbative structure of the proton can be factored out & confined to **universal** measurable parton distribution functions  $f_a(x, \mu_F^2)$  Collins, Soper, Sterman (1982-5)

and evolution of  $f_a(x, \mu_F^2)$  in factorisation scale calculable using the DGLAP equations, as we have seen earlier

# Drell-Yan in more detail

$$\frac{d\hat{\sigma}}{dM^2} \quad q\bar{q} \rightarrow l^+l^- = \frac{4\pi\alpha^2}{3N_c M^2} e_q^2 \delta(\hat{s} - M^2), \quad \hat{s} = x_1 x_2 s$$

$$\frac{d\sigma}{dM^2} = \frac{4\pi\alpha^2}{3N_c M^4} \tau \sum_q e_q^2 \int_0^1 dx_1 dx_2 \delta(x_1 x_2 - \tau) q(x_1) \bar{q}(x_2) + (q \leftrightarrow \bar{q})$$

$$\Rightarrow M^4 \frac{d\sigma}{dM^2} = \frac{4\pi\alpha^2}{3N_c} \tau \mathcal{F}(\tau) \quad \text{scaling!}$$

also

$$\frac{d\sigma}{dM^2 dy} = \frac{4\pi\alpha^2}{3N_c M^4} \tau \sum_q e_q^2 q(x_1) \bar{q}(x_2) + (q \leftrightarrow \bar{q}), \quad \tau = M^2/s$$

beyond leading order ...

$$d\hat{\sigma} = \hat{\sigma}_0 \left[ \delta(x_1 x_2 - \tau) + \frac{\alpha_s}{2\pi} \frac{\theta(x_1 x_2 - \tau)}{x_1 x_2} \left\{ f_q \left( \frac{\tau}{x_1 x_2} \right) + P \left( \frac{\tau}{x_1 x_2} \right) \ln \frac{M^2}{\kappa_1^2} + P \left( \frac{\tau}{x_1 x_2} \right) \ln \frac{M^2}{\kappa_2^2} \right\} \right]$$

### Note:

- collinear divergences, with same coefficients of logs as in DIS:  $P(x)$
- finite correction:  $f_q(x)$
- introduce a factorisation scale, as before:

$$\ln(M^2/\kappa^2) = \ln(M^2/\mu^2) + \ln(\mu^2/\kappa^2)$$

- then fold the parton-level cross section with  $q_0(x_1)$  and  $q_0(x_2)$ , and with the **same** ‘renormalised’ distributions as before\*, we obtain

$$d\sigma = \int_0^1 dx_1 dx_2 q(x_1, \mu^2) \bar{q}(x_2, \mu^2) \hat{\sigma}_0 [\delta(x_1 x_2 - \tau) + \frac{\alpha_s}{2\pi} \frac{1}{x_1 x_2} \left\{ \underbrace{2P \left( \frac{\tau}{x_1 x_2} \right) \ln \frac{M^2}{\mu^2}}_{\text{finite}} + \underbrace{f_q \left( \frac{\tau}{x_1 x_2} \right) - 2\bar{C} \left( \frac{\tau}{x_1 x_2} \right)}_{\text{finite}} \right\} + \mathcal{O}(\alpha_s^2)]$$

- the standard scale choice is  $\mu=M$

Altarelli et al  
Kubar et al  
1978-80

\*  $q(x, \mu^2) = q_0(x) + \frac{\alpha_s}{2\pi} \int_x^1 \frac{dy}{y} q_0(y) \left\{ P(x/y) \ln(\mu^2/\kappa^2) + \bar{C}(x/y) \right\}$

**Note:**

- the full calculation at  $O(\alpha_s)$  also includes
- which gives rise to  $\alpha_s q * g$  terms in the cross section (see QCD book)
- the (finite) correction is sometimes called the 'K-factor', it is generally large and positive
- ... and is factorisation scheme/scale dependent (to compensate the scheme dependence of the pdfs)

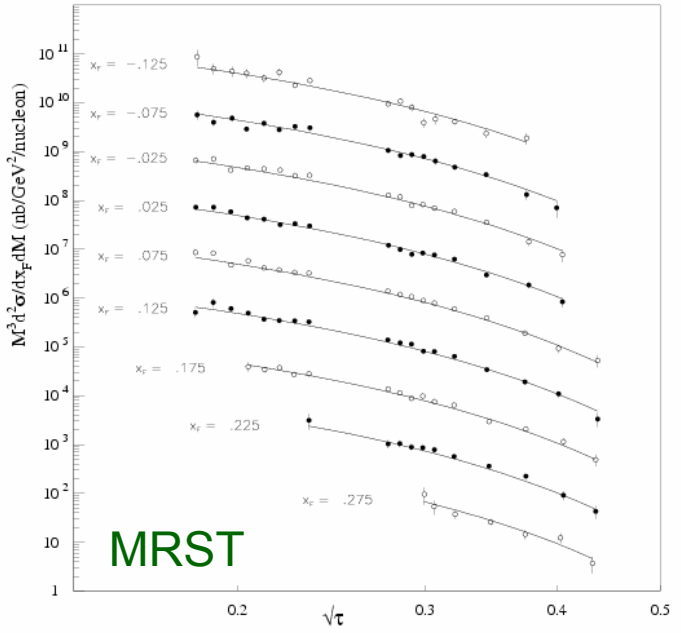

using high-precision Drell-Yan data to constrain the sea-quark pdfs

**Note:**  $x_F = \frac{2}{\sqrt{s}} (p_{l+} + p_{l-})_L \approx x_1 - x_2$

E605 (p Cu  $\rightarrow \mu^+ \mu^- X$ )  $P_{LAB} = 800$  GeV

# $pp \rightarrow \gamma^* + X$ Rapidity distribution

Anastasiou, Dixon, Melnikov, Petriello (hep-ph/0306192)

# the asymmetric sea

- the sea presumably arises when ‘primordial’ valence quarks emit gluons which in turn split into quark-antiquark pairs, with suppressed splitting into heavier quark pairs
- so we naively expect
$$\bar{u} \sim \bar{d} > s > c > b$$
- why such a big d-u asymmetry? meson cloud, Pauli exclusion, ...?
- and is  $s(x) = \bar{s}(x)$  ?

The ratio of Drell-Yan cross sections for  $pp, pn \rightarrow \mu^+\mu^- + X$  provides a measure of the difference between the  $u$  and  $d$  sea quark distributions

# W, Z cross sections: Tevatron and LHC

parton level  
cross sections  
(narrow width  
approximation)

$$\hat{\sigma}^{q\bar{q} \rightarrow Z} = \frac{4\pi\alpha}{3} \frac{v_q^2 + a_q^2}{4\sin^2\theta_W \cos^2\theta_W} \delta(\hat{s} - M_Z^2)$$

$$\hat{\sigma}^{q\bar{q}' \rightarrow W} = \frac{4\pi\alpha}{3} \frac{1}{4\sin^2\theta_W} \delta(\hat{s} - M_W^2)$$

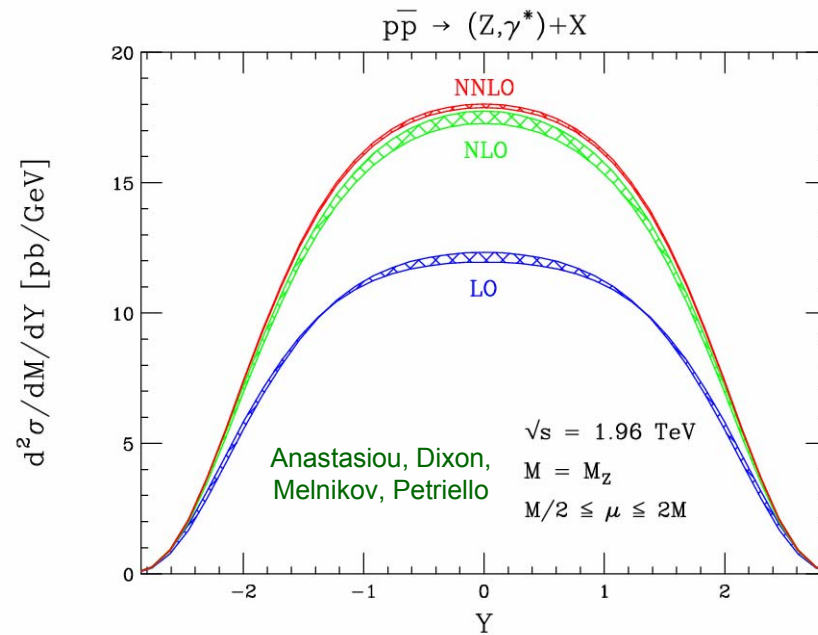

+ pQCD corrections to NNLO, EW to NLO

## CDF and DØ RunII Preliminary

# Z rapidity distribution at the Tevatron

# Drell-Yan as a probe of new physics

Large Extra Dimension models have new resonances which could contribute to Drell-Yan

⇒ need to understand the SM contribution to high precision!

Summary: the QCD **factorization theorem** for hard-scattering (short-distance) inclusive processes

$$\sigma_X = \sum_{a,b} \int_0^1 dx_1 dx_2 f_a(x_1, \mu_F^2) f_b(x_2, \mu_F^2) \times \hat{\sigma}_{ab \rightarrow X} \left( x_1, x_2, \{p_i^\mu\}; \alpha_S(\mu_R^2), \alpha(\mu_R^2), \frac{Q^2}{\mu_R^2}, \frac{Q^2}{\mu_F^2} \right)$$

where  $X=W, Z, H, \text{ high-}E_T \text{ jets, SUSY sparticles, black hole, ...}$ , and  $Q$  is the 'hard scale' (e.g.  $= M_X$ ), usually  $\mu_F = \mu_R = Q$ , and  $\hat{\sigma}$  is known ...

- to some fixed order in pQCD, e.g. high- $E_T$  jets

$$\hat{\sigma} = A\alpha_S^2 + B\alpha_S^3$$

- or in some leading logarithm approximation (LL, NLL, ...) to all orders via resummation

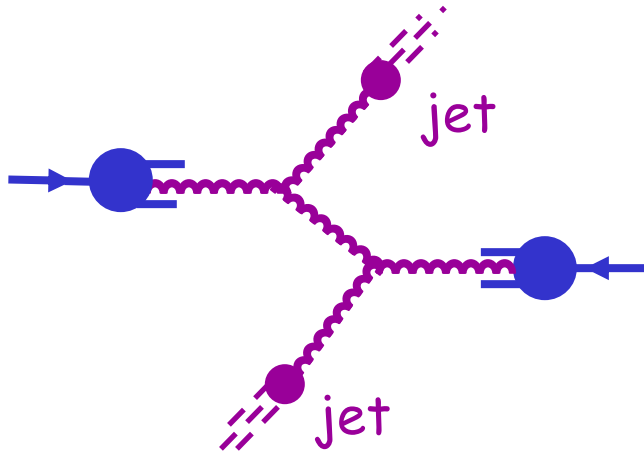

# High- $E_T$ jet production

$$E_J \frac{d\sigma}{d^3p_J} = \sum_{a,b,c,d=q,g} \int_0^1 dx_a dx_b f_{a/A}(x_a, Q^2) f_{b/B}(x_b, Q^2) \times \delta(\hat{s} + \hat{t} + \hat{u}) \frac{1}{16\pi^2 \hat{s}} |\overline{M}^{ab \rightarrow cd}|^2$$

see QCD book

- where  $ab \rightarrow cd$  represents all quark & gluon  $2 \rightarrow 2$  scattering processes

- NLO pQCD corrections also known

# jets at NNLO

$$\begin{aligned}
 \frac{d\sigma^{\text{jet}}}{dE_T} &= \alpha_s^2(\mu_R) A \\
 &+ \alpha_s^3(\mu_R) (B + 2b_0 L A) \\
 &+ \alpha_s^4(\mu_R) (C + 3b_0 L B + (3b_0^2 L^2 + 2b_1 L) A)
 \end{aligned}$$

$L = \ln(\mu_R/E_T)$

The NNLO coefficient  $C$  is not yet known, the curves show guesses  $C=0$  (solid),  $C=\pm B^2/A$  (dashed) → the scale dependence and hence  $\delta\sigma_{th}$  is significantly reduced

Tevatron jet inclusive cross section at  $E_T = 100$  GeV

Other advantages of NNLO:

- better matching of partons  
↔ hadrons
- reduced power corrections
- better description of final state kinematics (e.g. transverse momentum)

# jets at NNLO contd.

- 2 loop, 2 parton final state
- $|1 \text{ loop}|^2$ , 2 parton final state
- 1 loop, 3 parton final states  
or 2 + 1 final state
- tree, 4 parton final states  
or 3 + 1 parton final states  
or 2 + 2 parton final state

soft, collinear

⇒ rapid progress in recent years [many authors]

- many  $2 \rightarrow 2$  scattering processes with up to one off-shell leg now calculated at two loops
- ... to be combined with the tree-level  $2 \rightarrow 4$ , the one-loop  $2 \rightarrow 3$  and the self-interference of the one-loop  $2 \rightarrow 2$  to yield physical NNLO cross sections
- complete results expected 'soon'

# Higgs production

$$\hat{\sigma}^{gg \rightarrow H} = \frac{\alpha \alpha_S^2 M_H^2}{576 \sin^2 \theta_W M_W^2} \left| I \left( \frac{m_t^2}{M_H^2} \right) \right|^2$$

$$I(x) = 3x[2 + (4x - 1)F(x)]$$

$$F(x) = \theta(1 - 4x) \frac{1}{2} \left[ \log \left( \frac{1 + \sqrt{1 - 4x}}{1 - \sqrt{1 - 4x}} \right) - i\pi \right]^2 - \theta(4x - 1) 2 \left[ \sin^{-1}(1/2\sqrt{x}) \right]^2$$

- the HO pQCD corrections to  $\sigma(gg \rightarrow H)$  are large (more diagrams, more colour)

# top quark production

$$\hat{\sigma}_{q\bar{q}\rightarrow Q\bar{Q}} = \frac{\pi\alpha_S^2\beta\rho}{27M_Q^2}(2 + \rho)$$

$$\hat{\sigma}_{gg\rightarrow Q\bar{Q}} = \frac{\pi\alpha_S^2\beta\rho}{192M_Q^2}\left[\frac{1}{\beta}(\rho^2 + 16\rho + 16)\log\frac{1 + \beta}{1 - \beta} - 28 - 31\rho\right],$$

where  $\rho = 4M_Q^2/\hat{s}$ ,  $\beta = \sqrt{1 - \rho}$ .

NLO known, but awaits full NNLO pQCD calculation; NNLO & N<sup>n</sup>LL “soft+virtual” approximations exist

# parton luminosity functions

- a quick and easy way to assess the mass and collider energy dependence of production cross sections

$$\hat{\sigma}_{ab \rightarrow X} = C_X \delta(\hat{s} - M^2)$$

$$\sigma_X = \int_0^1 dx_a dx_b f_a(x_a, M^2) f_b(x_b, M^2) C_X \delta(x_a x_b - \tau)$$

$$\equiv C_X \left[ \frac{1}{s} \frac{\partial \mathcal{L}_{ab}}{\partial \tau} \right] \quad (\tau = M^2/s)$$

$$\frac{\partial \mathcal{L}_{ab}}{\partial \tau} = \int_0^1 dx_a dx_b f_a(x_a, M^2) f_b(x_b, M^2) \delta(x_a x_b - \tau)$$

- i.e. all the mass and energy dependence is contained in the X-independent parton luminosity function in [ ]
- useful combinations are  $ab = gg, \sum_q q\bar{q}, \dots$
- and also useful for assessing the uncertainty on cross sections due to uncertainties in the pdfs (see later)

- =  $gg$
- =  $\sum_i (gq_i + g\bar{q}_i + q_i g + \bar{q}_i g)$
- =  $\sum_i (q_i \bar{q}_i + \bar{q}_i q_i)$

see CHS for more

# future hadron colliders: energy vs luminosity?

recall parton-parton luminosity:

$$\frac{\partial \mathcal{L}_{ab}}{\partial \tau} = \int_{\tau}^1 \frac{dx}{x} f_a(x, Q^2) f_b(\tau/x, Q^2)$$

so that

$$\sigma_X \propto \frac{1}{s} \frac{\partial \mathcal{L}_{ab}}{\partial \tau}$$

with  $\tau = M_X^2/s$

for  $M_X > O(1 \text{ TeV})$ , energy  $\times 3$  is better than luminosity  $\times 10$  (everything else assumed equal!)

# what limits the precision of the predictions?

- the order of the perturbative expansion
- the uncertainty in the input parton distribution functions

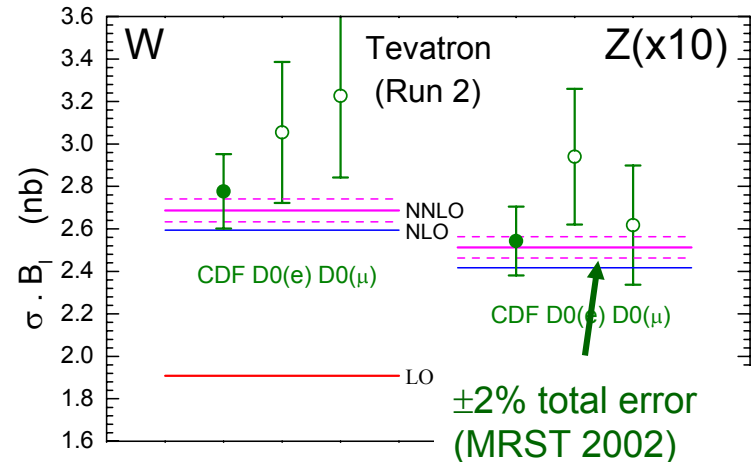

- **example:**  $\sigma(Z)$  @ LHC

$$\delta\sigma_{\text{pdf}} \approx \pm 3\%, \quad \delta\sigma_{\text{pt}} \approx \pm 2\%$$

$$\rightarrow \delta\sigma_{\text{theory}} \approx \pm 4\%$$

whereas for  $gg \rightarrow H$  :

$$\delta\sigma_{\text{pdf}} \ll \delta\sigma_{\text{pt}}$$

partons: MRST2002

NNLO evolution: van Neerven, Vogt approximation to Vermaseren et al. moments

NNLO  $W, Z$  corrections: van Neerven et al. with Harlander, Kilgore corrections

# pdf uncertainties

- MRST, CTEQ, Alekhin, ... also produce 'pdfs with errors'
- typically, 30-40 'error' sets based on a 'best fit' set to reflect  $\pm 1\sigma$  variation of all the parameters  $\{A_j, a_j, \dots, \alpha_S\}$  inherent in the fit
- these reflect the uncertainties on the **data** used in the global fit (e.g.  $\delta F_2 \approx \pm 3\% \rightarrow \delta u \approx \pm 3\%$ )
- however, there are also systematic pdf uncertainties reflecting theoretical assumptions/prejudices in the way the global fit is set up and performed

# uncertainty in gluon distribution (CTEQ)

CTEQ6.1E:

1 + 40 error sets

MRST2001E:

1 + 30 error sets

# high-x gluon from high $E_T$ jets data

- both MRST and CTEQ use Tevatron jets data to determine the gluon pdf at large x
- the errors on the gluon therefore reflect the measured cross section uncertainties

# why do 'best fit' pdfs and errors differ?

- different data sets in fit
  - different subselection of data
  - different treatment of exp. sys. errors
- different choice of
  - tolerance to define  $\pm \delta f_i$   
(MRST:  $\Delta\chi^2=50$ , CTEQ:  $\Delta\chi^2=100$ , Alekhin:  $\Delta\chi^2=1$ )
  - factorisation/renormalisation scheme/scale
  - $Q_0^2$
  - parametric form  $Ax^a(1-x)^b[..]$  etc
  - $\alpha_s$
  - treatment of heavy flavours
  - theoretical assumptions about  $x \rightarrow 0, 1$  behaviour
  - theoretical assumptions about sea flavour symmetry
  - evolution and cross section codes (removable differences!)

LHC	$\sigma_{\text{NLO}}(W)$ (nb)
MRST2002	204 ± 4 (expt)
CTEQ6	205 ± 8 (expt)
Alekhin02	215 ± 6 (tot)

similar partons  
different partons

different  $\Delta\chi^2$

Djouadi & Ferrag, hep-ph/0310209

**Note:** CTEQ gluon 'more or less' consistent with MRST gluon

- MRST:  $Q_0^2 = 1 \text{ GeV}^2$ ,  $Q_{\text{cut}}^2 = 2 \text{ GeV}^2$

$$xg = Ax^a(1-x)^b(1+Cx^{0.5}+Dx) - Ex^c(1-x)^d$$

- CTEQ6:  $Q_0^2 = 1.69 \text{ GeV}^2$ ,  $Q_{\text{cut}}^2 = 4 \text{ GeV}^2$

$$xg = Ax^a(1-x)^b e^{cx}(1+Cx)^d$$

# extrapolation errors

theoretical insight/guess:  $f \sim Ax$  as  $x \rightarrow 0$

theoretical insight/guess:  $f \sim \pm Ax^{-0.5}$  as  $x \rightarrow 0$

# tensions within the global fit

- with dataset A in fit,  $\Delta\chi^2=1$  ; with A and B in fit,  $\Delta\chi^2=?$
- 'tensions' between data sets arise, for example,
  - between DIS data sets (e.g.  $\mu\text{H}$  and  $\nu\text{N}$  data)
  - when jet and Drell-Yan data are combined with DIS data

# CTEQ $\alpha_s(M_Z)$ values from global analysis with $\Delta\chi^2 = 1, 100$

# beyond perturbation theory

non-perturbative effects arise in many different ways

- emission of gluons with  $k_T < Q_0$  off 'active' partons
- soft exchanges between partons of the same or different beam particles

manifestations include...

- hard scattering occurs at net non-zero transverse momentum
- 'underlying event' additional hadronic energy

precision phenomenology requires a quantitative understanding of these effects!

# 'intrinsic' transverse momentum

simple parton model assumes partons have zero transverse momentum

... but data shows that the DY lepton pair **is** produced with non-zero  $\langle p_T \rangle$

Generalise

$$d\xi f(\xi) \longrightarrow d^2k_T d\xi P(\vec{k}_T \xi),$$

$$\text{with } \int d^2k_T P(\vec{k}_T, \xi) = f(\xi).$$

If assume

$$P(\vec{k}_T, \xi) = h(\vec{k}_T) f(\xi)$$

then

$$\frac{1}{\sigma} \frac{d^2\sigma}{d^2p_T} = \int d^2k_{T1} d^2k_{T2} \delta^{(2)}(\vec{k}_{T1} + \vec{k}_{T2} - \vec{p}_T) h(\vec{k}_{T1}) h(\vec{k}_{T2})$$

A fit to data gives

$$h(\vec{k}_T) = \frac{b}{\pi} \exp(-bk_T^2)$$

$$\text{with } \langle k_T \rangle = (\pi/4b)^{1/2} = 760 \text{ MeV.}$$

the perturbative tail is even more apparent in  $W, Z$  production at the Tevatron, and can be well accounted for by the  $2 \rightarrow 2$  scattering processes:

$$\overline{\sum} |\mathcal{M}^{q\bar{q}' \rightarrow Wg}|^2 = \pi\alpha_S \sqrt{2} G_F M^2 |V_{qq'}|^2 \frac{8}{9} \frac{t^2 + u^2 + 2M^2 s}{tu}$$

$$\overline{\sum} |\mathcal{M}^{gq \rightarrow Wq'}|^2 = \pi\alpha_S \sqrt{2} G_F M^2 |V_{qq'}|^2 \frac{1}{3} \frac{s^2 + u^2 + 2tM^2}{-su}$$

... with known NLO pQCD corrections. Note that the  $p_T$  distribution diverges as  $p_T \rightarrow 0$  due to **soft gluon emission**:

$$\frac{d\sigma^R}{dp_T^2} = \alpha_S \left( A \frac{\ln(M^2/p_T^2)}{p_T^2} + B \frac{1}{p_T^2} + C(p_T^2) \right)$$

the  $O(\alpha_S)$  virtual gluon correction contributes at  $p_T=0$ , in such a way as to make the integrated distribution **finite**

$$\frac{d\sigma^{R+V}}{dp_T^2} = \alpha_S \left( A \left[ \frac{\ln(M^2/p_T^2)}{p_T^2} \right]_+ + B \left[ \frac{1}{p_T^2} \right]_+ + \bar{C}(p_T^2) \right)$$

intrinsic  $k_T$  can also be included, by convoluting with the pQCD contribution

# resummation

- when  $p_T \ll M$ , the pQCD series contains large logarithms  $\ln(M^2/p_T^2)$  at each order:

$$\frac{1}{\sigma} \frac{d\sigma}{dp_T^2} \simeq \frac{1}{p_T^2} \left[ A_1 \alpha_S \ln \frac{M^2}{p_T^2} + A_2 \alpha_S^2 \ln^3 \frac{M^2}{p_T^2} + \dots + A_n \alpha_S^n \ln^{2n-1} \frac{M^2}{p_T^2} + \dots \right]$$

which spoils the convergence of the series when  $\alpha_S \ln^2 \frac{M^2}{p_T^2} \sim 1$

- fortunately, these logarithms can be *resummed* to all orders in pQCD, to generate a **Sudakov form factor**:

$$\frac{1}{\sigma} \frac{d\sigma}{dp_T^2} \simeq \frac{d}{dp_T^2} \exp \left( -\frac{\alpha_S C_F}{2\pi} \ln^2 \frac{M^2}{p_T^2} \right) = \frac{\alpha_S C_F}{\pi} \frac{\ln(M^2/p_T^2)}{p_T^2} \exp \left( -\frac{\alpha_S C_F}{2\pi} \ln^2 \frac{M^2}{p_T^2} \right)$$

... which regulates the LO singularity at  $p_T = 0$

- the effect of the form factor is (just about) visible in the (Tevatron) data

# resummation contd.

- theoretical refinements include the addition of sub-leading logarithms (e.g. NNLL) and nonperturbative contributions, and merging the resummed contributions with the fixed order (e.g. NLO) contributions appropriate for large  $p_T$
- the resummation formalism is also valid for Higgs production at LHC via  $gg \rightarrow H$

- comparison of resummed / fixed-order calculations for Higgs ( $M_H = 125$  GeV)  $p_T$  distribution at LHC

Balazs et al, hep-ph/0403052

- differences due mainly to different  $N^n$ LO and  $N^n$ LL contributions included
- Tevatron  $d\sigma(Z)/dp_T$  provides good test of calculations

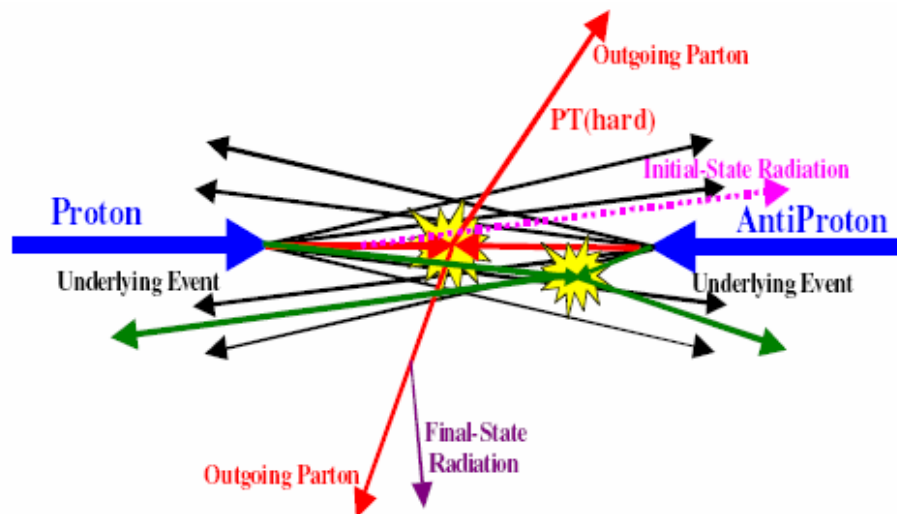

# full event simulation at hadron colliders

- it is important (designing detectors, interpreting events, etc.) to have a good understanding of **all** features of the collisions – not just the ‘hard scattering’ part
- this is very difficult because our understanding of the **non-perturbative** part of QCD is still quite primitive
- at present, therefore, we have to resort to **models** (PYTHIA, HERWIG, ...) ...

# Monte Carlo Event Generators

- programs that simulate particle physics events with the same probability as they occur in nature
- widely used for signal and background estimates
- the main programs in current use are **PYTHIA** and **HERWIG**
- the simulation comprises different phases:
  - start by simulating a hard scattering process – the fundamental interaction (usually a  $2 \rightarrow 2$  process but could be more complicated for particular signal/background processes)
  - this is followed by the simulation of (soft and collinear) QCD radiation using a **parton shower algorithm**
  - non-perturbative models are then used to simulate the hadronization of the quarks and gluons into the observed hadrons and the underlying event

# (hadron collider) processes in HERWIG

1300	$q\bar{q} \rightarrow Z^0/\gamma \rightarrow q\bar{q}$ (all flavours)	2800	$W^+W^-$ production in hadron-hadron collisions
1300+IQ	$q\bar{q} \rightarrow Z^0/\gamma \rightarrow q\bar{q}$ (IQ = 1, 2, 3, 4, 5, 6 for $q = d, u, s, c, b, t$ )	2810	$Z^0Z^0$ production in hadron-hadron collisions (including photon terms)
1350	$q\bar{q} \rightarrow Z^0/\gamma \rightarrow \ell\bar{\ell}$ (all lepton species)	2815	$Z^0Z^0$ production in hadron-hadron collisions ( $Z^0$ only)
1350+IL	$q\bar{q} \rightarrow Z^0/\gamma \rightarrow \ell\bar{\ell}$ (IL = 1, 2, 3 for $\ell = e, \mu, \tau$ )	2820	$W^\pm Z^0$ production in hadron-hadron collisions (including photon terms)
1399	$q\bar{q} \rightarrow Z^0/\gamma \rightarrow \text{anything}$	2825	$W^\pm Z^0$ production in hadron-hadron collisions ( $Z^0$ only)
1400	$q\bar{q} \rightarrow W^\pm \rightarrow q\bar{q}^*$ (all flavours)	2850	hadron-hadron $\rightarrow W^+W^-X$ using MC@NLO
1400+IQ	$q\bar{q} \rightarrow W^\pm \rightarrow q\bar{q}^*$ ( $q$ or $q^*$ as above)	2860	hadron-hadron $\rightarrow Z^0Z^0X$ using MC@NLO
1450	$q\bar{q} \rightarrow W^\pm \rightarrow b\tau$ (all lepton species)	2870	hadron-hadron $\rightarrow W^+Z^0X$ using MC@NLO
1450+IL	$q\bar{q} \rightarrow W^\pm \rightarrow b\tau$ (IL = 1, 2, 3 for $\ell = e, \mu, \tau$ )	2880	hadron-hadron $\rightarrow W^+Z^0X$ using MC@NLO
1499	$q\bar{q} \rightarrow W^\pm \rightarrow \text{anything}$	2900+IQ	$gg + g\bar{g} \rightarrow QQZ^0$ for massless $Q$ and $Q$ (IQ=1...6 for $Q = d, \dots, t$ )
1500	QCD 2 $\rightarrow$ 2 hard parton scattering	2910+IQ	$gg + g\bar{g} \rightarrow QQZ^0$ for massive $Q$ and $Q$ (IQ=1...6 for $Q = d, \dots, t$ )
	After generation, IHPPRO is subprocess (see sect. 4.6.2)	3000-3999	Minimal Supersymmetric Standard Model (MSSM) processes

4120	$u, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}, d, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}$ (all charginos)
4120+IC	$u, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}, d, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}$ (IC as above)
4130	$u, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}, d, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}$
4140	$u, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}, d, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}$ and $\tilde{d}, \tilde{d}, \tilde{s}$ and $\tilde{d}, \tilde{d}, \tilde{s}$ via $\tilde{u}, \tilde{d}, \tilde{s}$
4150	$u, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}, d, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}$ and $\tilde{d}, \tilde{d}, \tilde{s}$ via UDD.
4160	$u, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}, d, d, s \rightarrow \tilde{u}, \tilde{d}, \tilde{s}$ via UDD.
4200-99	Graviton resonance production
4200	Sum of 4210, 4250 and 4270
4210	$gg/q\bar{q} \rightarrow G \rightarrow gg/q\bar{q}$ (all partons)
4210+IQ	$gg/q\bar{q} \rightarrow G \rightarrow gg/q\bar{q}$ (IQ as above)
4220	$gg/q\bar{q} \rightarrow G \rightarrow gg$
4250	$gg/q\bar{q} \rightarrow G \rightarrow \ell\ell$ (all leptons)
4250+IL	$gg/q\bar{q} \rightarrow G \rightarrow \ell\ell$ (IL = 1 - 6 for $\ell = e, \mu, \tau, \nu_e, \nu_\mu, \nu_\tau$ , etc.)
4260	$gg/q\bar{q} \rightarrow G \rightarrow \gamma\gamma$
4270	$gg/q\bar{q} \rightarrow G \rightarrow W^+W^-/Z^0Z^0/H_{SM}^0/H_{SM}^\pm$
4271	$gg/q\bar{q} \rightarrow G \rightarrow W^+W^-$
4272	$gg/q\bar{q} \rightarrow G \rightarrow Z^0Z^0$
4273	$gg/q\bar{q} \rightarrow G \rightarrow H_{SM}^0/H_{SM}^\pm$

## however ...

- the tuning of the nonperturbative parts of the models is performed a single collider energy (or limited range of energies) – can we trust the extrapolation to LHC?!
- in general the event generators only use leading order matrix elements and therefore the normalisation is uncertain
- this can be overcome by renormalising to known NLO etc results or by incorporating next-to-leading order matrix elements (real + virtual emissions) – see below
- only soft and collinear emission is accounted for in the parton shower, therefore the emission of additional hard, high  $E_T$  jets is generally significantly underestimated
- for this reason, it is possible that many of the previous LHC studies of new physics signals have significantly underestimated the Standard Model backgrounds

# interfacing $N^n$ LO and parton showers

Benefits of both:

- $N^n$ LO** correct overall rate, hard scattering kinematics, reduced scale dep.
- PS** complete event picture, correct treatment of collinear logs to all orders

**Example:** MC@NLO  
 Frixione, Webber, Nason,  
[www.hep.phy.cam.ac.uk/theory/webber/MCatNLO/](http://www.hep.phy.cam.ac.uk/theory/webber/MCatNLO/)  
 processes included so far ...  
 $pp \rightarrow WW, WZ, ZZ, bb, tt, H^0, W, Z, \gamma$

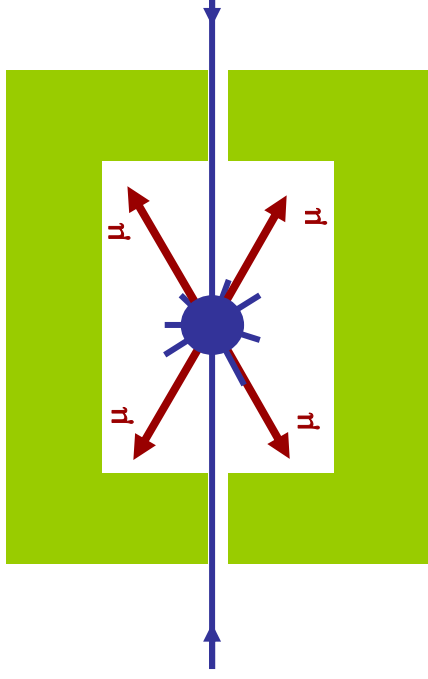

$p_T$  distribution of  $t\bar{t}$  at Tevatron

and finally ...

# central exclusive diffractive physics

# forward proton tagging at LHC: the physics case

- all objects produced this way must be in a  $0^{++}$  state  $\rightarrow$  spin-parity filter/analyser
- with a mass resolution of  $\sim O(1 \text{ GeV})$  from the proton tagging, the Standard Model  $H \rightarrow bb$  decay mode opens up, with  $S/B > 1$
- $H \rightarrow WW^{(*)}$  also looks very promising
- in certain regions of **MSSM** parameter space,  $S/B > 20$ , and double proton tagging is **THE** discovery channel

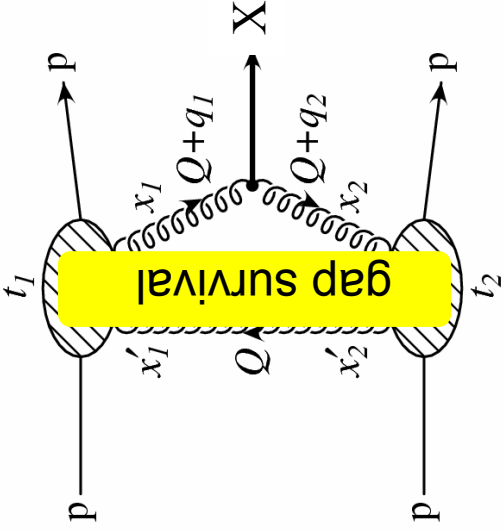

e.g. SM Higgs  $\rightarrow bb$   
 $\Delta M = 1 \text{ GeV}, L = 30 \text{ fb}^{-1}$

	S	B
$m_h = 120 \text{ GeV}$	11	4
$m_H = 130.5 \text{ GeV}$	144	4
$m_A = 130 \text{ GeV}$	1	2

- in other regions of MSSM parameter space, explicit CP violation in the Higgs sector shows up as an **azimuthal asymmetry** in the tagged protons  $\rightarrow$  direct probe of CP structure of Higgs sector at LHC
- **any** exotic  $0^{++}$  state, which couples strongly to glue, is a real possibility: radions, gluinoballs, ...

# the challenges ...

theory

need to calculate **production amplitude** and **gap Survival Factor**:  
 mix of **pQCD** and **npQCD**  $\Rightarrow$   
 significant uncertainties

experiment

# summary

- thanks to > 30 years theoretical studies, supported by experimental measurements, we now know how to calculate (an important class of) proton-proton collider event rates reliably and with a high precision
- the key ingredients are the factorisation theorem and the universal parton distribution functions
- such calculations underpin searches (at the **Tevatron** and the **LHC**) for Higgs, SUSY, etc
- ...but much work still needs to be done, in particular
  - calculating more and more NNLO pQCD corrections (and some missing NLO ones too) – see **Lance Dixon's lectures**
  - further refining the pdfs, and understanding their uncertainties
  - understanding the detailed **event structure**, which is outside the domain of pQCD and is currently simply modelled
  - extending the calculations to new types of New Physics production processes, e.g. **exclusive/diffractive production**
